

Waterbody: Northeast Drainage Ditch

Basin: Lake Lafayette

The Northeast Drainage Ditch is a heavily urbanized stream located within the City of Tallahassee. The stream flows east and eventually enters Upper Lake Lafayette. Directly upstream of the water quality sampling station is a stormwater facility known as Weems Pond Regional Stormwater Treatment Facility (Weems Pond). The City of Tallahassee is currently converting Weems Pond into an alum facility, which is scheduled to be online in 2015. The retrofit of the facility will reduce pollutant loads leaving the pond, which flow downstream through the Northeast Drainage Ditch and into Upper Lake Lafayette.

Portions of the Northeast Drainage Ditch west of Weems Road were historically altered for mosquito control and/or drainage purposes. The greatly altered flow conditions create channel scour during storms, and also contribute to low base flow east of Weems Road. The area east of Weems Road is physically unaltered; however, effects of the upstream modifications are reflected in the reduced quality of the biological community.

As shown in the following pie chart, approximately 72% of land use in the Northeast Drainage Ditch watershed is agricultural, residential, industrial and

transportation. Increases in stormwater runoff, and waterbody nutrient loads can often be attributed to these types of land uses.

Background

Healthy, well-balanced stream communities may be maintained with some level of human activity, but excessive human disturbance may result in waterbody degradation. Human stressors may include increased inputs of nutrients, sediments, and/or other contaminants from watershed runoff, adverse hydrologic alterations, undesirable removal of habitat or riparian buffer vegetation, and introduction of exotic plants and animals. Water quality standards are designed to protect designated uses of the waters of the state (*e.g.*, recreation, aquatic life, fish consumption), and exceedances of these standards are associated with interference of the designated use.

In late 2006, the U.S. Environmental Protection Agency (EPA) set a Total Maximum Daily Load (TMDL) target for fecal and total coliforms. The TMDL establishes the allowable loadings to the creek that would restore the creek to applicable water quality thresholds. In this case, fecal coliforms would have to be reduced by 63% to meet the criterion of fecal coliforms not exceeding 400 Most Probable Number (MPN) in 10 percent of the samples. When the TMDL was established, the EPA expected a reduction of 52% to meet the criterion for total

coliform. However, there is no longer a standard for total coliforms in Florida; therefore, only the fecal coliform criterion applies.

Methods

Surface water samples were collected to determine the health of the Northeast Drainage Ditch and met the requirements of the Florida Department of Environmental Protection (FDEP).

Results

Nutrients

Due to low water conditions, FDEP data requirements for the Numeric Nutrient Criteria could not be met for 2006 through 2008 and from 2010 through 2011 (Table 1). When requirements were met, nutrient values did not exceed the state criteria.

Table1. FDEP's chlorophyll *a*, total nitrogen and phosphorus criteria for streams applied to the Northeast Drainage Ditch.

Northeast Drainage Ditch	Total Nitrogen Threshold 1.03 mg/L	Total Phosphorus Threshold 0.18 mg/L
2006-2008	-	-
2009	0.17	0.07
2010-2011	-	-
2012	0.81	0.10
2013	0.30	0.09

Fecal coliforms

As mentioned previously, the EPA set a fecal coliform TMDL for the Northeast Drainage Ditch. While fecal coliforms were elevated above the 400/100 mL Class III limit in 14% of the samples for

Class III waters, there has not been an exceedance since December of 2009.

Other Parameters

Other water quality parameters appear to be normal for the area and no impairments were noted.

Conclusions

Based on ongoing sampling, the Northeast Drainage Ditch met the nutrient thresholds for the East Panhandle Region. While fecal coliforms were elevated above the 400/100 mL Class III limit in 14% of the samples for Class III waters, there has not been an exceedance since December of 2009. The greatly altered flow conditions create channel scour during storms and contribute to low base flow east of Weems Road. This physically unaltered segment reflects the hydraulic impacts with an impacted biological community. Other water quality parameters appear to be normal for the area and no impairments were noted.

Thank you for your interest in maintaining the quality of Leon County's water resources. Please feel free to contact us if you have any questions.
